Architecting for Reliability on AWS

ARCHITECTING FOR AVAILABILITY

Reliability or resiliency

The ability of an application to avoid and recover from failure

Availability

The percentage of time that an application is performing as expected

Poor performance implies low availability

Uptime isn't the same as availability

Decide how much availability you need before designing your AWS environment

Availability and Annual Downtime

99.0% 99.99% 99.99%

3 days 5 hours About 1 hour 5 minutes
15 hours 45 minutes

Architecting for 99.9% Availability

Traditional Application

Runs on Windows or Linux

You can "lift and shift" it to AWS without changing its code

- Example: SQL-backed web application

How you design for availability depends on the architecture of the application

Web-based Video Processing Application

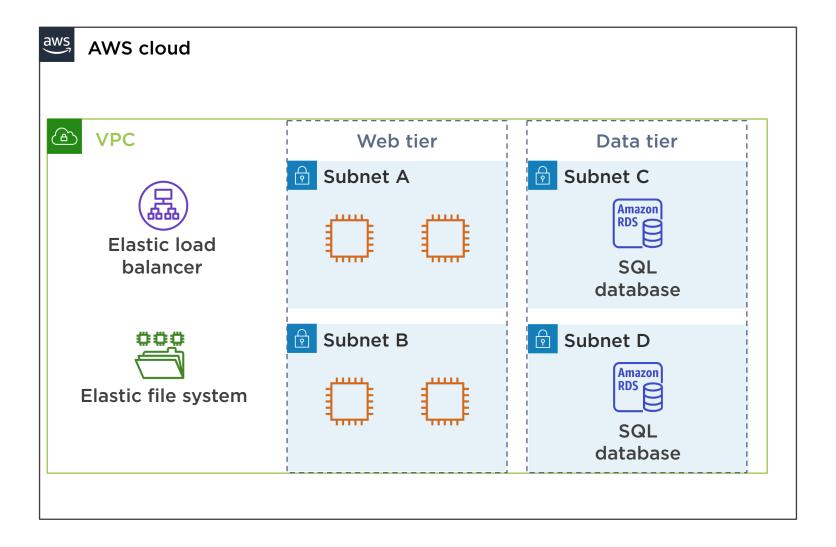

Front end

- Web interface
- Video processing logic

Back end

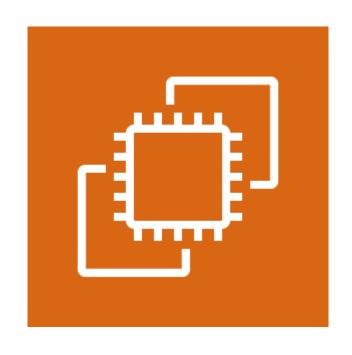

- SQL database

AWS Architecture

Calculating Availability—EC2

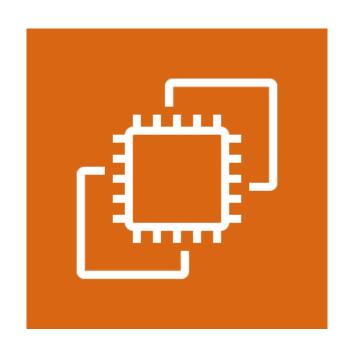

The service level agreement (SLA) for each service includes its annual availability

Availability of an EC2 instance is 90%

Failure rate of each instance is 10%

Calculating Availability—Redundant Instances

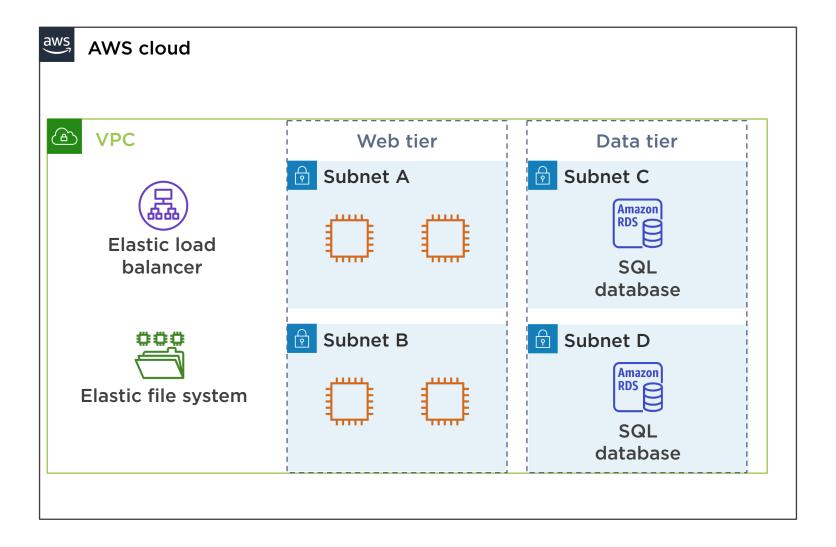

Multiply failure rate of four instances

 $-10\% \times 10\% \times 10\% \times 10\% = 0.01\%$

Subtract product from 100%

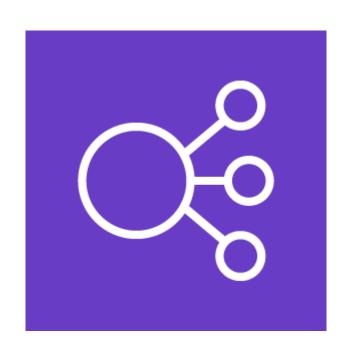

-100% - 0.01% = 99.99%

AWS Architecture

Calculating Availability—Elastic Load Balancer

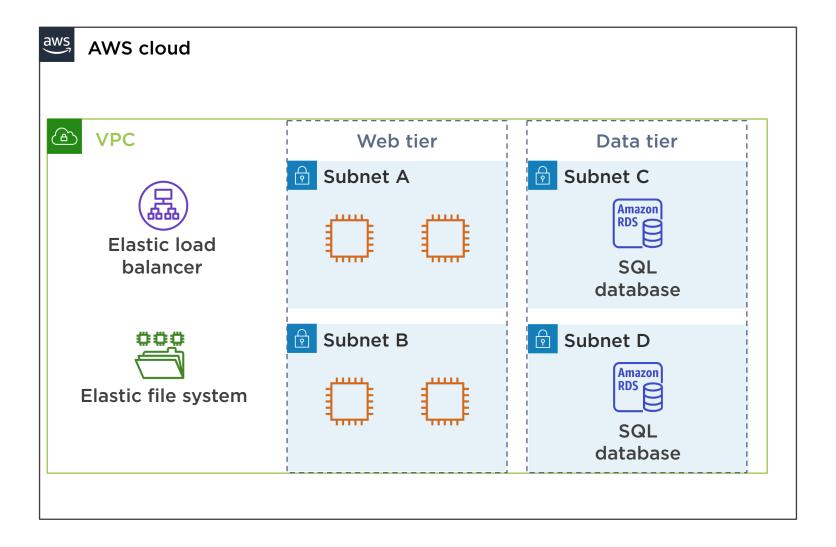

ELB availability is 99.99%

Multiply this by the availability of instances

- 99.99% × 99.99% = 99.998%

AWS Architecture

Calculating Availability—Elastic File System

EFS availability is 99.99%

99.998% × 99.99% = 99.97%

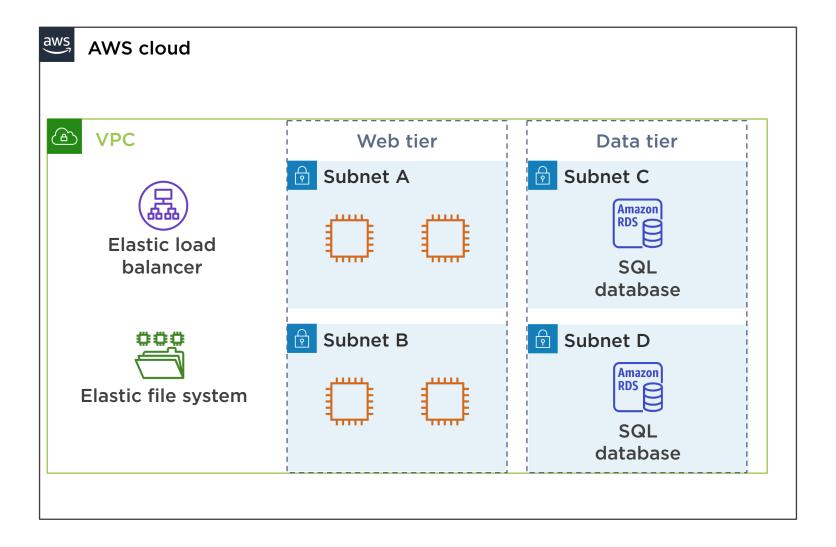

EFS or S3?

To use S3, application must be designed for it

EFS provides a network file system (NFS) volume

NFS is an established standard that most Linux distributions support

AWS Architecture

Relational Database Service

RDS offers managed database engines

- MySQL, MariaDB, PostgreSQL, Microsoft SQL server, and Oracle

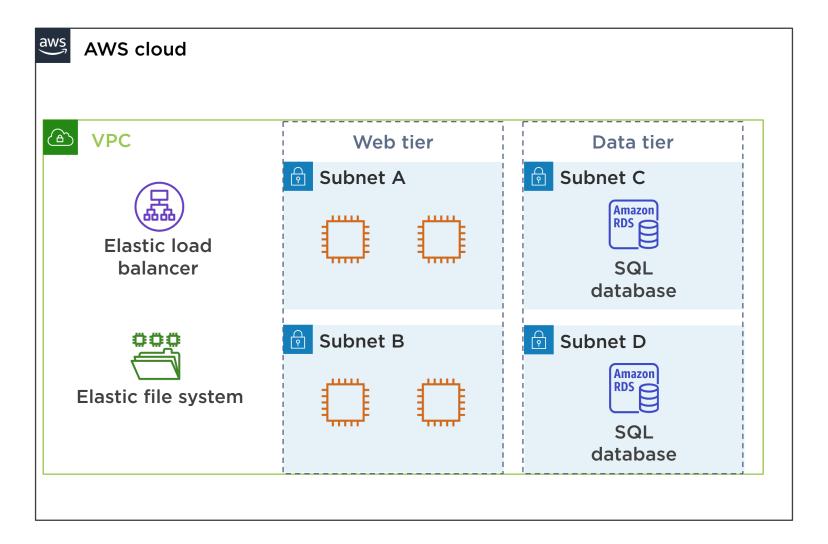

AWS manages database infrastructure and backups

Calculating Availability—RDS

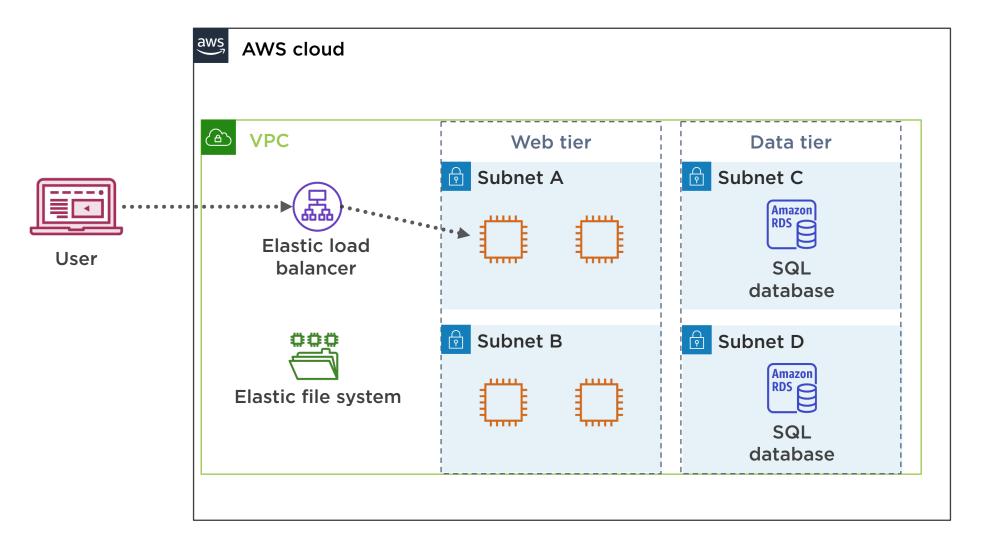

RDS multi-AZ availability is 99.95%

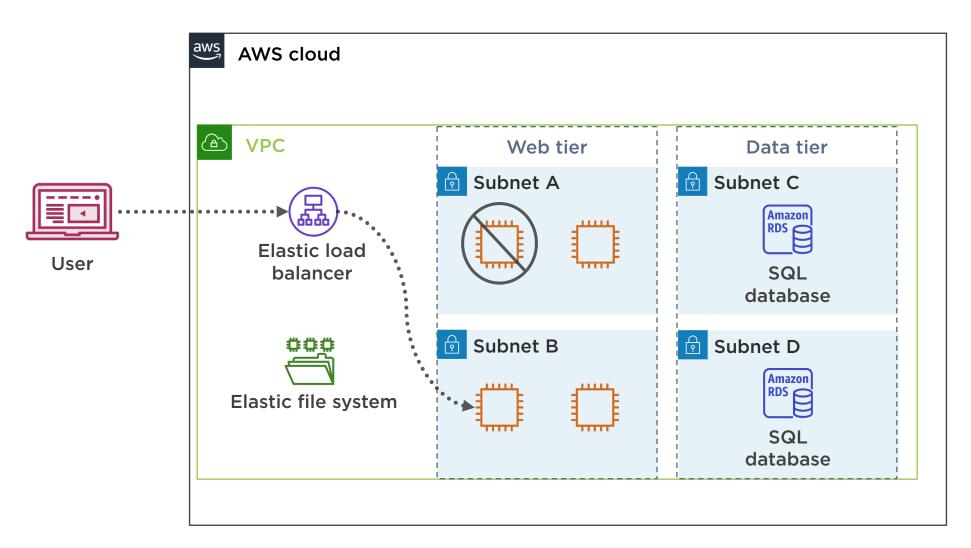

99.95% × 99.97% = 99.92%

Loose vs. Tight Coupling

Loose coupling

One component *doesn't* depend on a specific component

URL points to ELB

One-to-many relationship

Tight coupling

One component *does* depend on a specific component

URL points directly to instance

One-to-one relationship

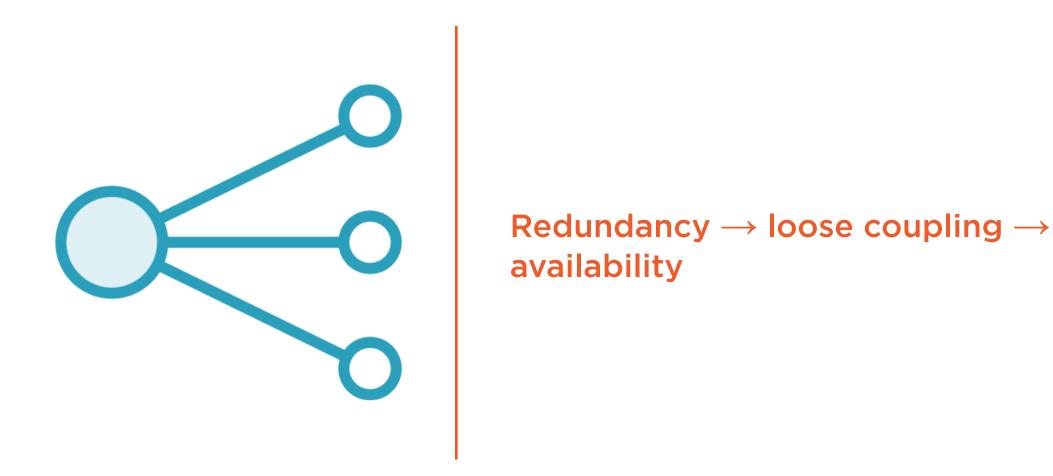

What About EFS?

Elastic services are always composed of redundant components

Elastic services are always loosely coupled with other resources

Redundancy and Loose Coupling

Loose Coupling and Performance

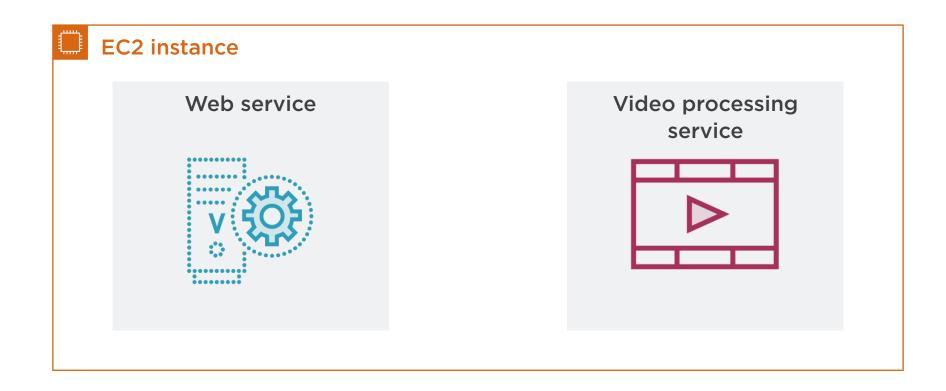

Independently scale resources without impacting availability

Performance and availability are linked

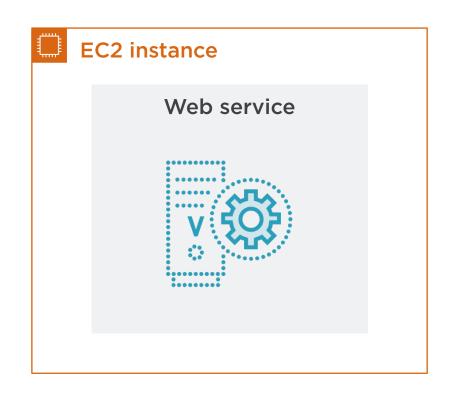

- Poor performance leads to low availability
- Good performance helps maintain availability

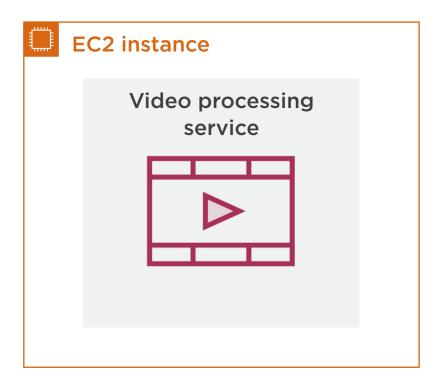

Simple Queue Service

Monolithic Architecture

Microservices Architecture

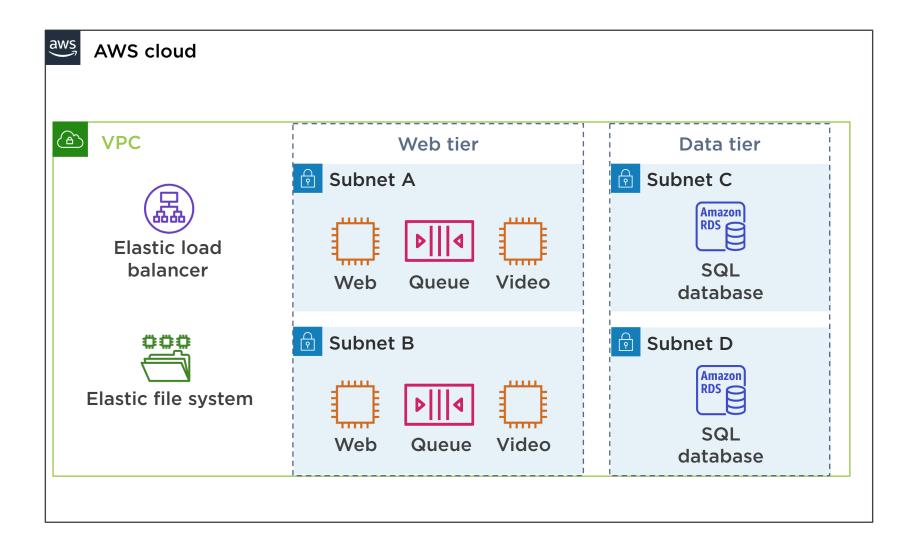

Benefits of Microservices **Easier updates**

Availability

Scalability

Microservices Architecture

Elastic Container Service

Containers

Behave like virtual machines

Let you run multiple microservices on a single instance

Processes running inside the container are isolated from the host

Docker

Image contains everything the service needs

Launch containers from an image

Like launching EC2 instances from an AMI

Benefits of Containers—Ease of Deployment

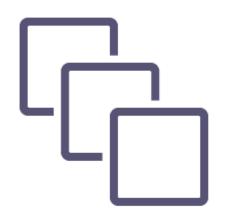

Build an image

Deploy it to instances

Launch containers from it

Benefits of Containers—Availability

Having multiple containers on a single instance can give you redundancy

Elastic Container Service

ECS clusters contain EC2 instances

ECS can store containers in an elastic container registry (ECR)

Elastic Container Service

A task defines how to launch containers

- Image to use
- CPU
- Memory
- Instance-to-container port mappings
- Storage mappings

Cloud Native Applications

Cloud Native Applications

Depend on a cloud service that can't be deployed on-premises

- Examples: SQS, S3, DynamoDB

"Services instead of servers"

Availability not necessarily higher than traditional applications

Cloud Native Application Example

Lambda Video processing

S3
Web asset and video storage

DynamoDB Database

Lambda

Managed "serverless" compute service

Supports many programming languages

- C#
- Java
- Python
- Go
- PowerShell

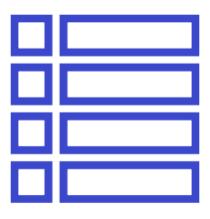

Availability is 99.95%

Simple Storage Service (S3)

Unlimited file storage
Static web hosting
Availability is 99.9%

DynamoDB

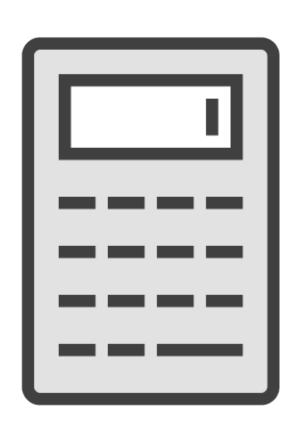

Managed, nonrelational database

Global tables feature replicates tables across multiple regions

Availability with global tables is 99.999%

Calculating Availability

Multiply the availability of services

 $-99.95 \times 99.9 \times 99.999 = 99.85\%$

Cloud Native Architecture

Advantages

Scalability

Performance

Convenience

Disadvantages

Cloud vendor lock-in

Slightly lower availability

Improve Availability by Using Multiple Regions

Calculate the failure rate of each region

- 100% — 99.85% = 0.15%

Multiply the failure rate of both regions

 $-0.15\% \times 0.15\% = 0.0225\%$

Subtract the product from 100%

 $-100\% - 0.0225\% \approx 99.999\%$

Trusted Advisor

Service Limits

You can't provision an unlimited number of AWS resources because of service limits

Check Trusted Advisor to find out your service limits

Demo

View Trusted Advisor to see how many EC2 instances we can launch per region

Key Takeaways

Availability is the percentage of time an application is performing as expected

Decide your availability requirements before beginning your design

To achieve high availability, use

- Redundancy
- Loose coupling

To calculate the availability of redundant components

- Multiply the failure rate of the components
- Subtract that number from 100%

To calculate the availability of hard dependencies, multiply the availability of the components together

The Simple Queue Service (SQS) can act as a go-between for loosely coupled services

- Sending service places message in a queue
- Receiving service polls the queue for new messages

Useful for online voting applications

The Elastic Container Service (ECS) deploys microservices using Docker containers

Can improve availability by running multiple containers on a single instance

Service limits constrain availability

Use Trusted Advisor to assess utilization against service limits
